## EE 105 Homework 4

Due 5pm, October 42019

## Problem 1: Door closer

A basic automatic door closer uses a torsion spring to pull the door closed and a damper to prevent the door from swinging too fast and slamming shut.
Assume the door has a moment of inertia, $I$, of $10 \mathrm{~kg} \cdot \mathrm{~m}^{2}$. This roughly represents a 30 kg door. The rotational damper has a damping force proportional to the angular velocity of the door, $B=30 \mathrm{~N} \cdot \mathrm{~m} / \frac{\mathrm{rad}}{\mathrm{sec}}$, and the spring constant $K$ is $22.5 \mathrm{~N} \cdot \mathrm{~m} / \mathrm{rad}$.
a) The door is opened to an angle of $60^{\circ}$ and released from a standstill. Use MatLab to plot the angle for $t=0$ to 5 s .
b) Can you improve the performance of the door closer, so that it closes faster without slamming? If so, explain how; if not, provide some mathematical justification as to why the current performance is optimal.

## Problem 2: Switching power supply

The schematic below shows a simple buck converter, which steps a voltage down from $V_{d d}$ to $V_{\text {out }}$ without wasting much energy. Other power supplies (including 110 V power adapters for charging phones and such) work on a similar principle.

We can approximate the diode and transistor with a voltage source that has a constant DC offset ( $V_{d d}$. duty cycle) and a sine wave with peak-to-peak amplitude of $V_{d d} .{ }^{1}$ For simplicity, let's assume the duty cycle is $50 \%$; i.e., we're stepping the voltage down from $V_{d d}$ down to $V_{d d} / 2$. Thus, we can write the input

$$
V_{i n}=V_{d d}\left(0.5+\cos \left(2 \pi f_{\text {switch }} \cdot t\right)\right)
$$

where $f_{\text {switch }}$ is the switching frequency in Hz .

[^0]You should already have the state-space and transfer function for this system from HW 2. You can crosscheck your answers with Matlab.
a) Find the forced/external response (i.e., the response to the input, assuming zero initial state). This will have two components, one corresponding to each of the two components of the input. Hint: You can use Matlab's step command to sanity-check the constant-input part of your answer.
b) Plot the external response for $V_{d d}=5 \mathrm{~V}, f_{\text {switch }}=10 \mathrm{kHz}, C=50 \mu \mathrm{~F}, L=5 \mathrm{mH}, R=5 \Omega$, for at least 10 ms . Include your code and plot in your submission.
c) Use Simulink to check your result, and include a plot from Simulink. Note that you can use Matlab workspace variables as parameters for your Simulink simulation.
d) Experiment with some different values of C and L , and comment on what happens. ${ }^{2}$ Can you speed up the transient response so the power supply turns on faster? What are the tradeoffs?
It turns out this is a major challenge in power supply design and control - check out "The Kat Kim show" on YouTube for videos on both control theory and power electronics. (https://www.youtube. com/user/katkimshow/videos)

## Problem 3: State space to transfer function

Consider the system described by

$$
\begin{gathered}
{\left[\begin{array}{l}
\dot{x}_{1} \\
\dot{x}_{2}
\end{array}\right]=\left[\begin{array}{cc}
-4 & 1 \\
3 & -1
\end{array}\right]\left[\begin{array}{l}
x_{1} \\
x_{2}
\end{array}\right]+\left[\begin{array}{l}
1 \\
1
\end{array}\right] u} \\
y=\left[\begin{array}{ll}
1 & 0
\end{array}\right]\left[\begin{array}{l}
x_{1} \\
x_{2}
\end{array}\right]
\end{gathered}
$$

a) Write the transfer function for this system. You should work this out by hand, but you can (and should) check your result with Matlab.
b) Is the system internally stable?

## Problem 4: Block diagrams

The block diagram below represents a system in "control canonical form".

a) Find the transfer function for the system. Note that $a_{n}$ and $b_{n}$ are constants.
b) Find a state-space representation of this system. This should be easy.

[^1]The block diagram below represents a system in "observer canonical form".

(b)
c) Find the transfer function for the system.
d) Find a state-space representation of this system. Again, this should be easy.
e) Write the transfer function for the block diagram below.

(d)

## Problem 5: Reflection

a) Approximately how long did you spend on this problem set?
b) What questions do you have about this problem set, or about the course material so far?

[^0]:    ${ }^{1}$ The actual diode/transistor combination will produce a square wave, but the constant and sine wave are the first two terms if we take the Fourier transform.

[^1]:    ${ }^{2}$ Assume $R$ is fixed, because this represents the load.
